Introduction

Motivation

Aim of the paper

To develop new inference methods that allow to *identify* and *locate* differences between nonparametric trend curves with dependent errors.

Research question: Out of many given intervals, how to find those where the trends are significantly different?

Why is it relevant?

Finding systematic differences between trends = basis for further research

Why is it difficult?

Testing many hypotheses at the same time = multiple testing problem

⇒ large probability of one true null hypothesis being rejected.

Is it limited to one application?

No! Our method = general method for comparing nonparametric trends

⇒ new statistical test for equality of nonparametric trend curves.

Comparison of deterministic trends:

- Park et al. (2009), Degras et al. (2012), Zhang et al. (2012), Hidalgo and Lee (2014), Chen and Wu (2019).

Multiscale tests:

- Chaudhuri and Marron (1999, 2000), Hall and Heckman (2000), Dümbgen and Spokoiny (2001), Park et al. (2009).

Comparison of volatility trends:

- Nyblom and Harvey (2000), ...

Model

We observe a panel of n time series $\mathcal{Z}_i = \{(Y_{it}, \mathbf{X}_{it}) : 1 \leq t \leq T\}$ of length T , where $Y_{it} \in \mathbb{R}$ and $\mathbf{X}_{it} \in \mathbb{R}^d$.

We assume the following model:

$$Y_{it} = m_i\left(\frac{t}{T}\right) + \beta_i^T \mathbf{X}_{it} + \alpha_i + \varepsilon_{it},$$

where

- m_i are unknown trend functions on $[0, 1]$;
- β_i is $d \times 1$ vector of unknown parameters;
- α_i are so-called fixed effect error terms;
- $\mathcal{E}_i = \{\varepsilon_{it} : 1 \leq t \leq T\}$ is a zero-mean stationary and causal error process.

$$Y_{it} = m_i\left(\frac{t}{T}\right) + \beta_i^\top \mathbf{X}_{it} + \alpha_i + \varepsilon_{it},$$

If we knew α_i and β_i , then the model becomes much simpler:

$$\begin{aligned} Y_{it} - \alpha_i - \beta_i^\top \mathbf{X}_{it} &=: Y_{it}^\circ \\ &= m_i\left(\frac{t}{T}\right) + \varepsilon_{it}. \end{aligned}$$

In reality the variables Y_{it}° are **not** observed.

But given $\hat{\alpha}_i$ and $\hat{\beta}_i$, we can consider

$$\hat{Y}_{it} := Y_{it} - \hat{\alpha}_i - \hat{\beta}_i^\top \mathbf{X}_{it} = (\beta_i - \hat{\beta}_i)^\top \mathbf{X}_{it} + m_i\left(\frac{t}{T}\right) + (\alpha_i - \hat{\alpha}_i) + \varepsilon_{it}.$$

Model, part 3

1. We estimate β_i :

$$\hat{\beta}_i = \left(\sum_{t=2}^T \Delta \mathbf{x}_{it} \Delta \mathbf{x}_{it}^\top \right)^{-1} \sum_{t=2}^T \Delta \mathbf{x}_{it} \Delta Y_{it}$$

Theorem

Under certain regularity assumptions, $\hat{\beta}_i$ is a consistent estimator of β_i with the property $\beta_i - \hat{\beta}_i = O_P(T^{-1/2})$.

2. We estimate the fixed effects α_i :

$$\hat{\alpha}_i = \frac{1}{T} \sum_{t=1}^T (Y_{it} - \hat{\beta}_i^\top \mathbf{x}_{it})$$

We then work with the augmented time series $\hat{Y}_{it} = Y_{it} - \hat{\alpha}_i - \hat{\beta}_i^\top \mathbf{x}_{it}$.

Testing procedure

$$H_0 : m_1 = m_2 = \dots = m_n$$

Question: if we reject the global null, how to locate the differences between the trends?

Consider a grid $\mathcal{G}_T = \{(u, h) : [u - h, u + h] \subseteq [0, 1]\}$ of location-bandwidth parameters. For each pair (i, j) and for each interval $[u - h, u + h]$ we consider the null hypothesis

$$H_0^{[i,j]}(u, h) : m_i(w) = m_j(w) \text{ for all } w \in [u - h, u + h].$$

Then the global null $H_0 : m_1 = m_2 = \dots = m_n$ can be reformulated as

$$H_0 : \text{The hypotheses } H_0^{[i,j]}(u, h) \text{ hold true for all intervals } [u - h, u + h], (u, h) \in \mathcal{G}_T, \text{ and for all } 1 \leq i < j \leq n.$$

Test statistic

For a given location $u \in [0, 1]$ and bandwidth h and a given pair (i, j) we construct the kernel averages

$$\hat{\psi}_{ij,T}(u, h) = \sum_{t=1}^T w_{t,T}(u, h) (\hat{Y}_{it} - \hat{Y}_{jt}),$$

where

$$w_{t,T}(u, h) = \frac{\Lambda_{t,T}(u, h)}{\{\sum_{t=1}^T \Lambda_{t,T}^2(u, h)\}^{1/2}},$$

$$\Lambda_{t,T}(u, h) = K\left(\frac{t/T - u}{h}\right) \left[S_{T,2}(u, h) - S_{T,1}(u, h) \left(\frac{t/T - u}{h}\right) \right],$$

$$S_{T,\ell}(u, h) = \frac{1}{Th} \sum_{t=1}^T K\left(\frac{t/T - u}{h}\right) \left(\frac{t/T - u}{h}\right)^\ell$$

for $\ell = 1, 2$ and K is a kernel function.

Test statistic, part 2

The kernel averages $\hat{\psi}_{ij,\tau}(u, h)$ measure the distance between two trend curves m_i and m_j on $[u - h, u + h]$.

Instead with working directly with $\hat{\psi}_{ij,\tau}(u, h)$, we replace them by

$$\hat{\psi}_{ij,\tau}^0(u, h) = \left\{ \left| \frac{\hat{\psi}_{ij,\tau}(u, h)}{(\hat{\sigma}_i^2 + \hat{\sigma}_j^2)^{1/2}} \right| - \lambda(h) \right\},$$

where

- $\hat{\sigma}_i^2$ is an appropriate estimator of the long-run variance σ_i^2 ;
- $\lambda(h) = \sqrt{2 \log\{1/(2h)\}}$ is an additive correction term (Dümbgen and Spokoiny (2001)).

Explanation

To test the global null, we aggregate the individual test statistics for all (i, j) and all location-bandwidth pairs $(u, h) \in \mathcal{G}_T$:

$$\widehat{\Psi}_{n,T} = \max_{1 \leq i < j \leq n} \max_{(u,h) \in \mathcal{G}_T} \widehat{\psi}_{ij,T}^0(u, h).$$

Note

Under certain conditions and under the null, $\widehat{\psi}_{ij,T}^0(u, h)$ and $\widehat{\Psi}_{n,T}$ can be approximated by the corresponding Gaussian versions of the test statistics.

Gaussian version of the individual test statistics:

$$\phi_{ij,T}^0(u, h) = \max_{(u,h) \in \mathcal{G}_T} \left\{ \left| \frac{\phi_T(u, h)}{(\sigma_i^2 + \sigma_j^2)^{1/2}} \right| - \lambda(h) \right\},$$

where

- $\phi_T(u, h) = \sum_{t=1}^T w_{t,T}(u, h) \{ \sigma_i(Z_{it} - \bar{Z}_i) - \sigma_j(Z_{jt} - \bar{Z}_j) \};$
- Z_{it} are independent standard normal random variables;
- \bar{Z}_i is the empirical average of Z_{i1}, \dots, Z_{iT} .

Aggregated Gaussian test statistics:

$$\Phi_{n,T} = \max_{1 \leq i < j \leq n} \max_{(u,h) \in \mathcal{G}_T} \phi_{ij,T}^0(u, h).$$

Test procedure, part 2

1. Consider the Gaussian test statistic

$$\Phi_{n,T} = \max_{1 \leq i < j \leq n} \max_{(u,h) \in \mathcal{G}_T} \phi_{ij,T}^0(u,h),$$

where ϕ_{ijk}^0 are weighted averages of the differences of standard normal random variables.

2. Compute a $(1 - \alpha)$ -quantile $q_{n,T}(\alpha)$ of $\Phi_{n,T}$ by Monte Carlo simulations.
3. Perform the test for the global hypothesis H_0 : reject H_0 if $\hat{\Psi}_{n,T} > q_{n,T}(\alpha)$.
4. For each i, j , and each $(u, h) \in \mathcal{G}_T$, carry out the test for the local null hypothesis $H_0^{[i,j]}(u, h)$: reject $H_0^{[i,j]}(u, h)$ if $\hat{\psi}_{ij,T}^0(u, h) > q_{n,T}(\alpha)$.

Theoretical properties

Assumptions

C1 The variables ε_t are weakly dependent.

C2 It holds that $\|\varepsilon_t\|_q < \infty$ for some $q > 4$.

C3 Standard assumptions on the kernel function K .

C4 $|\mathcal{G}_T| = O(T^\theta)$ for some arbitrarily large but fixed constant $\theta > 0$.

$$\mathcal{G}_T = \{(u, h) : u = t/T \text{ for some } 1 \leq t \leq T \text{ and } h \in [h_{\min}, h_{\max}] \\ \text{with } h = t/T \text{ for some } 1 \leq t \leq T\},$$

C5 $h_{\min} \gg T^{-(1-\frac{2}{q})} \log T$ and $h_{\max} = o(1)$.

C6 Assume that $\hat{\sigma}^2 = \sigma^2 + o_p(\rho_T)$ with $\rho_T = o(1/\log T)$.

Assumptions

C1 The functions λ_i are uniformly Lipschitz continuous:

$$|\lambda_i(u) - \lambda_i(v)| \leq L|u - v| \text{ for all } u, v \in [0, 1].$$

C2 $0 < \lambda_{\min} \leq \lambda_i(w) \leq \lambda_{\max} < \infty$ for all $w \in [0, 1]$ and all i .

C3 η_{it} are independent both across i and t .

C4 $\mathbb{E}[\eta_{it}] = 0$, $\mathbb{E}[\eta_{it}^2] = 1$ and $\mathbb{E}[|\eta_{it}|^\theta] \leq C_\theta < \infty$ for some $\theta > 4$.

C5 $h_{\max} = o(1/\log T)$ and $h_{\min} \geq CT^{-b}$ for some $b \in (0, 1)$.

C6 $p := \{\#(i, j, k)\} = O(T^{(\theta/2)(1-b)-(1+\delta)})$ for some small $\delta > 0$.

Theoretical properties

Proposition

Let \mathcal{M}_0 be the set of triplets (i, j, k) for which $H_0^{(ijk)}$ holds true. Then under $\mathcal{C}1 - \mathcal{C}6$, it holds that

$$\mathbb{P}\left(\forall (i, j, k) \in \mathcal{M}_0 : |\hat{\psi}_{ijk}| \leq c_{\text{Gauss}}(\alpha, h_k)\right) \geq 1 - \alpha + o(1)$$

Proposition

Consider a sequence of functions $\lambda_i = \lambda_{i,T}$, $\lambda_j = \lambda_{j,T}$ such that

$$\exists \mathcal{I}_k : \lambda_i(w) - \lambda_j(w) \geq c_T \sqrt{\log T / (Th_k)} \quad \forall w \in \mathcal{I}_k, \quad (1)$$

and $c_T \rightarrow \infty$ faster than $\frac{\sqrt{\log T} \sqrt{\log \log T}}{\log \log \log T}$. Let \mathcal{M}_1 be the set of triplets (i, j, k) for which (1) holds true. Then under $\mathcal{C}1 - \mathcal{C}6$, it holds that

$$\mathbb{P}\left(\forall (i, j, k) \in \mathcal{M}_1 : |\hat{\psi}_{ijk}| > c_{\text{Gauss}}(\alpha, h_k)\right) = 1 - o(1)$$

Strategy of the proof

- Replace the statistic $\widehat{\Psi}_T$ under $H_0 : m = 0$ by a statistic $\widetilde{\Phi}_T$ with the same distribution and the property that

$$|\widetilde{\Phi}_T - \Phi_T| = o_p(\delta_T),$$

where $\delta_T = o(1)$. To do so, we make use of strong approximation theory for dependent processes as derived in Berkes et al. (2014)

- Using the anti-concentration results for Gaussian random vectors (Chernozhukov et al. 2015), prove that Φ_T does not concentrate too strongly in small regions of the form $[x - \delta_T, x + \delta_T]$, i.e.

$$\sup_{x \in \mathbb{R}} P(|\Phi_T - x| \leq \delta_T) = o(1).$$

- Show that

$$\sup_{x \in \mathbb{R}} |P(\widetilde{\Phi}_T \leq x) - P(\Phi_T \leq x)| = o(1).$$

Application

Graphical representation

How to represent the results of the test?

Plot the results of pairwise comparison $\mathcal{F}_{\text{reject}}(i, j)$:

$$P\left(\forall (i, j, k) \in \mathcal{M}_0 : \mathcal{I}_k \notin \mathcal{F}_{\text{reject}}(i, j)\right) \geq 1 - \alpha + o(1)$$

Minimal intervals

An interval $\mathcal{I}_k \in \mathcal{F}_{\text{reject}}(i, j)$ is called **minimal** if there is no other interval $\mathcal{I}_{k'} \in \mathcal{F}_{\text{reject}}(i, j)$ with $\mathcal{I}_{k'} \subset \mathcal{I}_k$.

The set of minimal intervals is denoted $\mathcal{F}_{\text{reject}}^{\min}(i, j)$.

We can make similar confidence statements about minimal intervals:

$$P\left(\forall (i, j, k) \in \mathcal{M}_0 : \mathcal{I}_k \notin \mathcal{F}_{\text{reject}}^{\min}(i, j)\right) \geq 1 - \alpha + o(1)$$

We can claim, with confidence of about 95%, that the null hypothesis is violated for all intervals (and all pairs of time series) for which our test rejects the null.

However, we can not say anything about the causes of such differences. This question requires further (probably not purely statistical) analysis.

Further possible extensions:

- introduce scaling factor in the trend function, that will allow to adjust for the size of the country (population, density, testing regimes, etc.);
- include the dependence between covariates and error terms;
- cluster the time series based on the trends they exhibit.

Thank you!

$T = 500$	0.996	0.905	0.947	0.998	0.964	0.928	0.996	0.989	0.932

Estimator of σ^2

We estimate the overdispersion parameter σ^2 by

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n \hat{\sigma}_i^2 \text{ and } \hat{\sigma}_i^2 = \frac{\sum_{t=2}^T (X_{it} - X_{it-1})^2}{2 \sum_{t=1}^T X_{it}}$$

We assume that λ_i is Lipschitz continuous. Then

$$X_{it} - X_{it-1} = \sigma \sqrt{\lambda_i \left(\frac{t}{T} \right)} (\eta_{it} - \eta_{it-1}) + r_{it},$$

where $|r_{it}| \leq C(1 + |\eta_{it-1}|)/T$ with a sufficiently large C . Hence,

$$\frac{1}{T} \sum_{t=2}^T (X_{it} - X_{it-1})^2 = 2\sigma^2 \left\{ \frac{1}{T} \sum_{t=2}^T \lambda_i(t/T) \right\} + o_p(1)$$

Together with

$$\frac{1}{T} \sum_{t=1}^T X_{it} = \frac{1}{T} \sum_{t=1}^T \lambda_i(t/T) + o_p(1),$$

we get that $\hat{\sigma}_i^2 = \sigma^2 + o_p(1)$ for any i and thus $\hat{\sigma}^2 = \sigma^2 + o_p(1)$.

Idea behind a_k and b_k

Dümbgen and Spokoiny (2001): the critical values $c_{ijk}(\alpha)$ depend on the scale of the testing problem, i.e. the length h_k of the time interval.

Specifically,

$$c_{ijk}(\alpha) = c(\alpha, h_k) := b_k + q(\alpha)/a_k,$$

where $a_k = \{\log(e/h_k)\}^{1/2} / \log \log(e^e/h_k)$ and $b_k = \sqrt{2 \log(1/h_k)}$ are scale-dependent constants and $q(\alpha)$ is chosen such that we control FWER.

Idea behind a_k and b_k , part 2

This choice of scale-dependent constants helps us balance the significance of hypotheses between the time intervals of different lengths h_k :

[Go back](#)

Idea behind the additive correction

Consider the uncorrected Gaussian statistic

$$\Phi^{\text{uncor}} = \max_{(i,j,k)} |\phi_{ijk}|$$

and let the family of intervals be

$$\mathcal{F} = \{[(m-1)h_l, mh_l] \text{ for } 1 \leq m \leq 1/h_l, 1 \leq l \leq L\}$$

Then we can rewrite the uncorrected test statistic as

$$\Phi^{\text{uncor}} = \max_{i,j} \max_{\substack{1 \leq l \leq L, \\ 1 \leq m \leq 1/h_l}} \left| \frac{1}{\sqrt{2Th_l}} \sum_{t=1}^T 1\left(\frac{t}{T} \in [(m-1)h_l, mh_l]\right) (Z_{it} - Z_{jt}) \right|$$

$\Rightarrow \max_m \dots = \sqrt{2 \log(1/h_l)} + o_P(1) \rightarrow \infty$ as $h \rightarrow 0$ and the stochastic behavior of Φ^{uncor} is dominated by the elements with small bandwidths h_l . [Go back](#)
