Introduction

Aim of the paper

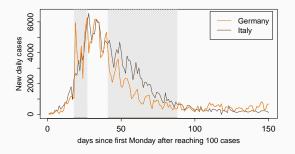

Aim of the paper

Aim of the paper

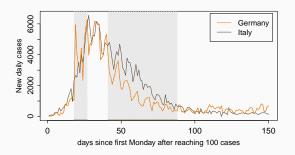

Aim of the paper

Aim of the paper

To develop new inference methods that allow to *identify* and *locate* differences between epidemic time trends.

Research question: Out of many given intervals, how to find those where the trends are significantly different?

Why is it relevant?

Finding systematic differences between trends = basis for further research

 \Rightarrow understanding which government policies are more effective.

Why is it relevant?

Finding systematic differences between trends = basis for further research

 \Rightarrow understanding which government policies are more effective.

Why is it difficult?

Testing many hypotheses at the same time = multiple testing problem

 \Rightarrow large probability of one true null hypothesis being rejected.

Why is it relevant?

Finding systematic differences between trends = basis for further research

 \Rightarrow understanding which government policies are more effective.

Why is it difficult?

Testing many hypotheses at the same time = multiple testing problem

 \Rightarrow large probability of one true null hypothesis being rejected.

Is it limited to COVID-19?

No! Our method = general method for comparing nonparametric trends

⇒ new statistical test for equality of nonparametric trend curves.

Comparison of deterministic trends:

 Park et al. (2009), Degras et al. (2012), Zhang et al. (2012), Hidalgo and Lee (2014), Chen and Wu (2019).

Comparison of deterministic trends:

 Park et al. (2009), Degras et al. (2012), Zhang et al. (2012), Hidalgo and Lee (2014), Chen and Wu (2019).

Comparison of deterministic trends:

 Park et al. (2009), Degras et al. (2012), Zhang et al. (2012), Hidalgo and Lee (2014), Chen and Wu (2019).

Multiscale tests:

Chaudhuri and Marron (1999, 2000), Hall and Heckman (2000),
 Dümbgen and Spokoiny (2001), Park et al. (2009).

Chaudhuri and Marron (1999, 2000), Hall and Heckman (2000),
 Dümbgen and Spokoiny (2001), Park et al. (2009).

Comparison of deterministic trends:

 Park et al. (2009), Degras et al. (2012), Zhang et al. (2012), Hidalgo and Lee (2014), Chen and Wu (2019).

Multiscale tests:

• Chaudhuri and Marron (1999, 2000), Hall and Heckman (2000), Dümbgen and Spokoiny (2001), Park et al. (2009).

Studies of COVID-19:

 Dong et al. (2020), Gu et al. (2020), Li and Linton (2020), Jiang et al. (2020) and many others.

We observe *n* time series $X_i = \{X_{it} : 1 \le t \le T\}$ of length T.

We observe *n* time series $\mathcal{X}_i = \{X_{it} : 1 \leq t \leq T\}$ of length T.

 X_{it} are non-negative integers \Rightarrow can be modelled by a Poisson distribution with time-varying parameter $\lambda_i(t/T)$: $X_{it} \sim P_{\lambda_i(t/T)}$.

We observe *n* time series $\mathcal{X}_i = \{X_{it} : 1 \leq t \leq T\}$ of length T.

 X_{it} are non-negative integers \Rightarrow can be modelled by a Poisson distribution with time-varying parameter $\lambda_i(t/T)$: $X_{it} \sim P_{\lambda_i(t/T)}$.

Since
$$\lambda_i(t/T)=\mathbb{E}[X_{it}]=\mathrm{Var}(X_{it})$$
, we can rewrite X_{it} as $X_{it}=\lambda_i\Big(rac{t}{T}\Big)+u_{it}$

We observe *n* time series $\mathcal{X}_i = \{X_{it} : 1 \leq t \leq T\}$ of length T.

 X_{it} are non-negative integers \Rightarrow can be modelled by a Poisson distribution with time-varying parameter $\lambda_i(t/T)$: $X_{it} \sim P_{\lambda_i(t/T)}$.

Since
$$\lambda_i(t/T) = \mathbb{E}[X_{it}] = \operatorname{Var}(X_{it})$$
, we can rewrite X_{it} as
$$X_{it} = \lambda_i \left(\frac{t}{T}\right) + \sqrt{\lambda_i \left(\frac{t}{T}\right)} \eta_{it},$$

where η_{it} has zero mean and unit variance.

We observe *n* time series $\mathcal{X}_i = \{X_{it} : 1 \leq t \leq T\}$ of length T.

 X_{it} are non-negative integers \Rightarrow can be modelled by a Poisson distribution with time-varying parameter $\lambda_i(t/T)$: $X_{it} \sim P_{\lambda_i(t/T)}$.

Since
$$\lambda_i(t/T) = \mathbb{E}[X_{it}] = \operatorname{Var}(X_{it})$$
, we can rewrite X_{it} as
$$X_{it} = \lambda_i \left(\frac{t}{T}\right) + \sqrt{\lambda_i \left(\frac{t}{T}\right)} \eta_{it},$$

where η_{it} has zero mean and unit variance.

In applications the variance can be larger than the mean \Rightarrow quasi-Poisson models.

Quasi-Poisson model:

$$X_{it} = \lambda_i \left(\frac{t}{T}\right) + \sigma \sqrt{\lambda_i \left(\frac{t}{T}\right)} \eta_{it},$$

Quasi-Poisson model:

$$X_{it} = \lambda_i \left(\frac{t}{T}\right) + \sigma \sqrt{\lambda_i \left(\frac{t}{T}\right)} \eta_{it},$$

where

• σ is the overdispersion parameter;

Quasi-Poisson model:

$$X_{it} = \lambda_i \left(\frac{t}{T}\right) + \sigma \sqrt{\lambda_i \left(\frac{t}{T}\right)} \eta_{it},$$

where

- σ is the overdispersion parameter;
- λ_i are unknown trend functions on [0, 1];

Quasi-Poisson model:

$$X_{it} = \lambda_i \left(\frac{t}{T}\right) + \sigma \sqrt{\lambda_i \left(\frac{t}{T}\right)} \eta_{it},$$

where

- σ is the overdispersion parameter;
- λ_i are unknown trend functions on [0, 1];
- η_{it} are error terms that are independent across i and t and have zero mean and unit variance.

Testing procedure

$$H_0: \lambda_1 = \lambda_2 = \ldots = \lambda_n$$

$$H_0: \lambda_1 = \lambda_2 = \ldots = \lambda_n$$

Question: if we reject the global null, how to locate the differences between the trends?

$$H_0: \lambda_1 = \lambda_2 = \ldots = \lambda_n$$

Question: if we reject the global null, how to locate the differences between the trends?

Let $\mathcal{F}:=\{\mathcal{I}_k\subseteq [0,1]:1\leq k\leq K\}$ be a family of rescaled time intervals on [0,1], and for each triplet (i,j,k) consider the null hypothesis that the functions λ_i and λ_j are equal on an interval \mathcal{I}_k

$$H_0: \lambda_1 = \lambda_2 = \ldots = \lambda_n$$

Question: if we reject the global null, how to locate the differences between the trends?

Let $\mathcal{F}:=\{\mathcal{I}_k\subseteq [0,1]: 1\leq k\leq K\}$ be a family of rescaled time intervals on [0,1], and for each triplet (i,j,k) consider the null hypothesis that the functions λ_i and λ_j are equal on an interval \mathcal{I}_k , i.e.

$$H_0^{(ijk)}: \quad \lambda_i(w) = \lambda_j(w) \text{ for all } w \in \mathcal{I}_k$$

$$H_0: \lambda_1 = \lambda_2 = \ldots = \lambda_n$$

Question: if we reject the global null, how to locate the differences between the trends?

Let $\mathcal{F}:=\{\mathcal{I}_k\subseteq [0,1]:1\leq k\leq K\}$ be a family of rescaled time intervals on [0,1], and for each triplet (i,j,k) consider the null hypothesis that the functions λ_i and λ_j are equal on an interval \mathcal{I}_k , i.e.

$$H_0^{(ijk)}: \quad \lambda_i(w) = \lambda_j(w) \text{ for all } w \in \mathcal{I}_k$$

We want to test $H_0^{(ijk)}$ simultaneously for all pairs of countries i and j and all intervals \mathcal{I}_k in the family \mathcal{F} and we want to control the familywise error rate (FWER) at level α :

$$FWER(\alpha) = P(\exists (i,j,k) : we wrongly reject H_0^{(ijk)}).$$

Nonparametric comparison of epidemic time trends: the case of COVID-19

For a given interval \mathcal{I}_k and a pair of time series i and j we calculate

$$\hat{s}_{ijk} = \frac{1}{Th_k} \sum_{t=1}^{T} 1\left(\frac{t}{T} \in \mathcal{I}_k\right) (X_{it} - X_{jt}),$$

where h_k is the length of \mathcal{I}_k .

For a given interval \mathcal{I}_k and a pair of time series i and j we calculate

$$\hat{s}_{ijk} = \frac{1}{Th_k} \sum_{t=1}^{T} 1\left(\frac{t}{T} \in \mathcal{I}_k\right) (X_{it} - X_{jt}),$$

where h_k is the length of \mathcal{I}_k . \hat{s}_{ijk} estimates the average distance between λ_i and λ_j on \mathcal{I}_k .

For a given interval \mathcal{I}_k and a pair of time series i and j we calculate

$$\hat{s}_{ijk} = \frac{1}{Th_k} \sum_{t=1}^{I} 1\left(\frac{t}{T} \in \mathcal{I}_k\right) (X_{it} - X_{jt}),$$

where h_k is the length of \mathcal{I}_k . \hat{s}_{ijk} estimates the average distance between λ_i and λ_j on \mathcal{I}_k . Under certain assumptions,

$$\operatorname{Var}(\hat{s}_{ijk}) = \frac{\sigma^2}{T^2 h_k^2} \sum_{t=1}^T 1\left(\frac{t}{T} \in \mathcal{I}_k\right) \left\{ \lambda_i \left(\frac{t}{T}\right) + \lambda_j \left(\frac{t}{T}\right) \right\},\,$$

For a given interval \mathcal{I}_k and a pair of time series i and j we calculate

$$\hat{s}_{ijk} = \frac{1}{Th_k} \sum_{t=1}^{T} 1\left(\frac{t}{T} \in \mathcal{I}_k\right) (X_{it} - X_{jt}),$$

where h_k is the length of \mathcal{I}_k . \hat{s}_{ijk} estimates the average distance between λ_i and λ_j on \mathcal{I}_k . Under certain assumptions,

$$\operatorname{Var}(\hat{s}_{ijk}) = \frac{\sigma^2}{T^2 h_k^2} \sum_{t=1}^T 1\left(\frac{t}{T} \in \mathcal{I}_k\right) \left\{\lambda_i\left(\frac{t}{T}\right) + \lambda_j\left(\frac{t}{T}\right)\right\},\,$$

which can be estimated by

$$\widehat{\mathrm{Var}(\widehat{s}_{ijk})} = \frac{\widehat{\sigma}^2}{T^2 h_k^2} \sum_{t=1}^T \mathbb{1}\Big(\frac{t}{T} \in \mathcal{I}_k\Big)(X_{it} + X_{jt}),$$

with $\hat{\sigma}^2$ being an appropriate estimator of σ^2 . Details

Test statistic, part 2

Test statistic for the hypothesis $H_0^{(ijk)}$ is then defined as

$$\widehat{\psi}_{ijk} := \frac{\widehat{s}_{ijk}}{\sqrt{\widehat{\operatorname{Var}}(\widehat{s}_{ijk})}} = \frac{\sum_{t=1}^{T} 1(\frac{t}{T} \in \mathcal{I}_k)(X_{it} - X_{jt})}{\widehat{\sigma}\{\sum_{t=1}^{T} 1(\frac{t}{T} \in \mathcal{I}_k)(X_{it} + X_{jt})\}^{1/2}}$$

Critical values

How to construct critical values $c_{ijk}(\alpha)$?

Critical values

How to construct critical values $c_{ijk}(\alpha)$?

• Traditional approach: $c_{ijk}(\alpha) = c(\alpha)$ for all (i, j, k).

Critical values

How to construct critical values $c_{ijk}(\alpha)$?

- Traditional approach: $c_{ijk}(\alpha) = c(\alpha)$ for all (i, j, k).
- More modern approach: $c_{ijk}(\alpha)$ depend on the length h_k of the time interval (Dümbgen and Spokoiny (2001)):

$$c_{ijk}(\alpha) = c(\alpha, h_k) := b_k + q(\alpha)/a_k,$$

where a_k and b_k are scale-dependent constants and $q(\alpha)$ is chosen such that we control FWER. Details

We want to control FWER.

We want to control FWER. Let $\mathcal{M}_0 := \{(i,j,k)|H_0^{(ijk)} \text{ is true}\}$, then

$$\mathsf{FWER}(\alpha) = \mathrm{P}\Big(\exists (i,j,k) \in \mathcal{M}_0 : |\widehat{\psi}_{ijk}| > c_{ijk}(\alpha)\Big)$$

We want to control FWER. Let $\mathcal{M}_0 := \{(i,j,k)|H_0^{(ijk)} \text{ is true}\}$, then

$$\begin{aligned} \mathsf{FWER}(\alpha) &= \mathsf{P}\Big(\exists (i,j,k) \in \mathcal{M}_0 : |\widehat{\psi}_{ijk}| > c_{ijk}(\alpha)\Big) \\ &= 1 - \mathsf{P}\Big(\forall (i,j,k) \in \mathcal{M}_0 : |\widehat{\psi}_{ijk}| \le c_{ijk}(\alpha)\Big) \\ &= 1 - \mathsf{P}\Big(\forall (i,j,k) \in \mathcal{M}_0 : a_k\big(|\widehat{\psi}_{ijk}| - b_k\big) \le q(\alpha)\Big) \\ &= 1 - \mathsf{P}\Big(\max_{(i,j,k) \in \mathcal{M}_0} a_k\big(|\widehat{\psi}_{ijk}| - b_k\big) \le q(\alpha)\Big) \\ &\le 1 - \mathsf{P}\Big(\max_{(i,j,k)} a_k\big(|\widehat{\psi}_{ijk}^0| - b_k\big) \le q(\alpha)\Big) \end{aligned}$$

We want to control FWER. Let $\mathcal{M}_0 := \{(i,j,k)|H_0^{(ijk)} \text{ is true}\}$, then

$$\begin{aligned} \mathsf{FWER}(\alpha) &= \mathsf{P}\Big(\exists (i,j,k) \in \mathcal{M}_0 : |\widehat{\psi}_{ijk}| > c_{ijk}(\alpha)\Big) \\ &= 1 - \mathsf{P}\Big(\forall (i,j,k) \in \mathcal{M}_0 : |\widehat{\psi}_{ijk}| \le c_{ijk}(\alpha)\Big) \\ &= 1 - \mathsf{P}\Big(\forall (i,j,k) \in \mathcal{M}_0 : a_k\big(|\widehat{\psi}_{ijk}| - b_k\big) \le q(\alpha)\Big) \\ &= 1 - \mathsf{P}\Big(\max_{(i,j,k) \in \mathcal{M}_0} a_k\big(|\widehat{\psi}_{ijk}| - b_k\big) \le q(\alpha)\Big) \\ &\le 1 - \mathsf{P}\Big(\max_{(i,j,k)} a_k\big(|\widehat{\psi}_{ijk}^0| - b_k\big) \le q(\alpha)\Big) \end{aligned}$$

We want to control FWER. Let $\mathcal{M}_0 := \left\{(i,j,k)|H_0^{(ijk)} \text{ is true}\right\}$, then

$$\begin{aligned} \mathsf{FWER}(\alpha) &= \mathsf{P}\Big(\exists (i,j,k) \in \mathcal{M}_0 : |\widehat{\psi}_{ijk}| > c_{ijk}(\alpha)\Big) \\ &= 1 - \mathsf{P}\Big(\forall (i,j,k) \in \mathcal{M}_0 : |\widehat{\psi}_{ijk}| \le c_{ijk}(\alpha)\Big) \\ &= 1 - \mathsf{P}\Big(\forall (i,j,k) \in \mathcal{M}_0 : a_k\big(|\widehat{\psi}_{ijk}| - b_k\big) \le q(\alpha)\Big) \\ &= 1 - \mathsf{P}\Big(\max_{(i,j,k) \in \mathcal{M}_0} a_k\big(|\widehat{\psi}_{ijk}| - b_k\big) \le q(\alpha)\Big) \\ &\le 1 - \mathsf{P}\Big(\max_{(i,j,k)} a_k\big(|\widehat{\psi}_{ijk}^0| - b_k\big) \le q(\alpha)\Big) \end{aligned}$$

Hence, we choose $q(\alpha)$ as the $(1-\alpha)$ -quantile of the statistic

$$\hat{\Psi}_T = \max_{(i,j,k)} a_k (|\hat{\psi}^0_{ijk}| - b_k),$$

where $\hat{\psi}^0_{iik}$ is equal to $\hat{\psi}_{ijk}$ under the null.

But we do not know the distribution of $\hat{\Psi}_{\mathcal{T}}$ in practice!

But we do not know the distribution of $\hat{\Psi}_{\mathcal{T}}$ in practice!

 \Rightarrow the quantiles $q(\alpha)$ are also not known. How to approximate them?

But we do not know the distribution of $\hat{\Psi}_{\mathcal{T}}$ in practice!

 \Rightarrow the quantiles $q(\alpha)$ are also not known. How to approximate them? Under our assumptions,

$$\hat{\psi}_{ijk}^0 pprox rac{1}{\sqrt{2Th_k}} \sum_{t=1}^T \mathbb{1}\Big(rac{t}{T} \in \mathcal{I}_k\Big) (\eta_{it} - \eta_{jt}),$$

can be approximated by a Gaussian version of the test statistic:

$$\phi_{ijk} = \frac{1}{\sqrt{2Th_k}} \sum_{t=1}^{T} 1\left(\frac{t}{T} \in \mathcal{I}_k\right) (Z_{it} - Z_{jt}),$$

where Z_{it} are independent standard normal random variables.

1. Consider the Gaussian test statistic

$$\Phi_T = \max_{(i,j,k)} a_k (|\phi_{ijk}| - b_k),$$

where a_k and b_k are scale-dependent constants and ϕ_{ijk} are weighted averages of the differences of standard normal random variables.

1. Consider the Gaussian test statistic

$$\Phi_T = \max_{(i,j,k)} a_k (|\phi_{ijk}| - b_k),$$

where a_k and b_k are scale-dependent constants and ϕ_{ijk} are weighted averages of the differences of standard normal random variables.

2. Compute a $(1 - \alpha)$ -quantile $q_{\mathsf{Gauss}}(\alpha)$ of Φ_T by Monte Carlo simulations.

1. Consider the Gaussian test statistic

$$\Phi_T = \max_{(i,j,k)} a_k (|\phi_{ijk}| - b_k),$$

where a_k and b_k are scale-dependent constants and ϕ_{ijk} are weighted averages of the differences of standard normal random variables.

- 2. Compute a (1α) -quantile $q_{\mathsf{Gauss}}(\alpha)$ of $\Phi_{\mathcal{T}}$ by Monte Carlo simulations.
- 3. Adjust $q_{Gauss}(\alpha)$ by the scale-dependent constants

$$c_{\mathsf{Gauss}}(\alpha, h_k) = b_k + q_{\mathsf{Gauss}}(\alpha)/a_k$$

1. Consider the Gaussian test statistic

$$\Phi_T = \max_{(i,j,k)} a_k (|\phi_{ijk}| - b_k),$$

where a_k and b_k are scale-dependent constants and ϕ_{ijk} are weighted averages of the differences of standard normal random variables.

- 2. Compute a (1α) -quantile $q_{\mathsf{Gauss}}(\alpha)$ of $\Phi_{\mathcal{T}}$ by Monte Carlo simulations.
- 3. Adjust $q_{Gauss}(\alpha)$ by the scale-dependent constants

$$c_{\mathsf{Gauss}}(\alpha, h_k) = b_k + q_{\mathsf{Gauss}}(\alpha)/a_k$$

Test procedure

For the given significance level $\alpha \in (0,1)$ and for each (i,j,k), reject $H_0^{(ijk)}$ if $|\widehat{\psi}_{ijk}| > c_{\text{Gauss}}(\alpha,h_k)$.

Theoretical properties, part 1

Proposition

Let \mathcal{M}_0 be the set of triplets (i, j, k) for which $H_0^{(ijk)}$ holds true. Then under certain assumptions, it holds that

$$P\Big(orall (i,j,k) \in \mathcal{M}_0 : |\hat{\psi}_{ijk}| \leq c_{\mathsf{Gauss}}(lpha,h_k) \Big) \geq 1 - lpha + o(1)$$

Theoretical properties, part 1

Proposition

Let \mathcal{M}_0 be the set of triplets (i, j, k) for which $H_0^{(ijk)}$ holds true. Then under certain assumptions, it holds that

$$P\Big(orall (i,j,k) \in \mathcal{M}_0 : |\hat{\psi}_{ijk}| \leq c_{\mathsf{Gauss}}(lpha,h_k) \Big) \geq 1 - lpha + o(1)$$

Corollary

$$FWER(\alpha) \leq \alpha$$
.

Theoretical properties, part 2

Proposition

Consider a sequence of functions $\lambda_i = \lambda_{i,T}$, $\lambda_j = \lambda_{j,T}$ such that

$$\exists \mathcal{I}_k : \lambda_i(w) - \lambda_j(w) \ge c_T \sqrt{\log T/(Th_k)} \ \forall w \in \mathcal{I}_k, \tag{1}$$

and $c_T \to \infty$ faster than $\frac{\sqrt{\log T}\sqrt{\log \log T}}{\log \log \log T}$. Let \mathcal{M}_1 be the set of triplets (i,j,k) for which (1) holds true. Then under certain assumptions, it holds that

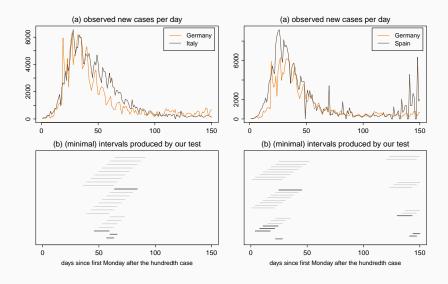

$$\mathrm{P}\Big(orall (i,j,k) \in \mathcal{M}_1: |\hat{\psi}_{ijk}| > c_{\mathsf{Gauss}}(lpha,h_k)\Big) = 1 - o(1)$$

Application

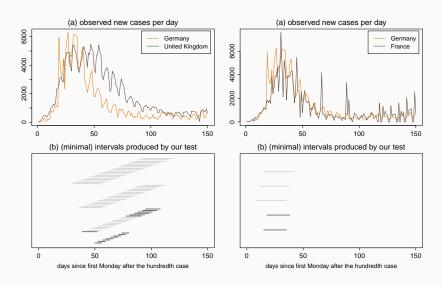

Application setting

- Five countries: Germany, Italy, Spain, France and the UK.
- T = 150 days.
- The data is aligned by weekdays: first Monday after reaching 100 cases as t = 1.
- Lengths of time intervals 7, 14, 21, 28 days. The intervals start at days 1, 8, 15, ... and 4, 11, 19, ...
- $\alpha = 0.05$.
- 5000 Monte Carlo simulation runs to produce critical values.

Application results

Application results, part 2

Discussion

We can claim, with confidence of about 95%, that the null hypothesis is violated for all intervals (and all pairs of countries) for which our test rejects the null.

Discussion

We can claim, with confidence of about 95%, that the null hypothesis is violated for all intervals (and all pairs of countries) for which our test rejects the null.

However, we can not say anything about the causes of such differences. This question requires further (probably not purely statistical) analysis.

Discussion

We can claim, with confidence of about 95%, that the null hypothesis is violated for all intervals (and all pairs of countries) for which our test rejects the null.

However, we can not say anything about the causes of such differences. This question requires further (probably not purely statistical) analysis.

Further possible extensions:

- introduce scaling factor in the trend function, that will allow to adjust for the size of the country (population, density, testing regimes, etc.);
- include dependence in the error terms;
- cluster the countries based on the trends they exhibit.

Thank you!

Assumptions

- C1 The functions λ_i are uniformly Lipschitz continuous: $|\lambda_i(u) \lambda_i(v)| \le L|u v|$ for all $u, v \in [0, 1]$.
- C2 $0 < \lambda_{\min} \le \lambda_i(w) \le \lambda_{\max} < \infty$ for all $w \in [0,1]$ and all i.
- C3 η_{it} are independent both across i and t.
- $\mathcal{C}4 \ \mathbb{E}[\eta_{it}] = 0, \ \mathbb{E}[\eta_{it}^2] = 1 \ \text{and} \ \mathbb{E}[|\eta_{it}|^\theta] \leq C_\theta < \infty \ \text{for some} \ \theta > 4.$
- $\mathcal{C}5$ $h_{\mathsf{max}} = o(1/\log T)$ and $h_{\mathsf{min}} \geq CT^{-b}$ for some $b \in (0,1)$.
- C6 $p := \{\#(i,j,k)\} = O(T^{(\theta/2)(1-b)-(1+\delta)})$ for some small $\delta > 0$.

Nonparametric comparison of epidemic time trends: the case of COVID-19

Estimator of σ^2

We estimate the overdispersion paramter σ^2 by

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n \hat{\sigma}_i^2 \text{ and } \hat{\sigma}_i^2 = \frac{\sum_{t=2}^T (X_{it} - X_{it-1})^2}{2 \sum_{t=1}^T X_{it}}$$

Estimator of σ^2

We estimate the overdispersion paramter σ^2 by

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n \hat{\sigma}_i^2 \text{ and } \hat{\sigma}_i^2 = \frac{\sum_{t=2}^T (X_{it} - X_{it-1})^2}{2 \sum_{t=1}^T X_{it}}$$

We assume that λ_i is Lipschitz continuous. Then

$$X_{it} - X_{it-1} = \sigma \sqrt{\lambda_i \left(\frac{t}{T}\right) (\eta_{it} - \eta_{it-1}) + r_{it}},$$

where $|r_{it}| \leq C(1+|\eta_{it-1}|)/T$ with a sufficiently large C.

Estimator of σ^2

We estimate the overdispersion paramter σ^2 by

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n \hat{\sigma}_i^2 \text{ and } \hat{\sigma}_i^2 = \frac{\sum_{t=2}^T (X_{it} - X_{it-1})^2}{2 \sum_{t=1}^T X_{it}}$$

We assume that λ_i is Lipschitz continuous. Then

$$X_{it} - X_{it-1} = \sigma \sqrt{\lambda_i \left(\frac{t}{T}\right) (\eta_{it} - \eta_{it-1}) + r_{it}},$$

where $|r_{it}| \leq C(1+|\eta_{it-1}|)/T$ with a sufficiently large C. Hence,

$$\frac{1}{T}\sum_{t=2}^{T}(X_{it}-X_{it-1})^2=2\sigma^2\left\{\frac{1}{T}\sum_{t=2}^{T}\lambda_i(t/T)\right\}+o_p(1)$$

Estimator of σ^2

We estimate the overdispersion paramter σ^2 by

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n \hat{\sigma}_i^2 \text{ and } \hat{\sigma}_i^2 = \frac{\sum_{t=2}^T (X_{it} - X_{it-1})^2}{2 \sum_{t=1}^T X_{it}}$$

We assume that λ_i is Lipschitz continuous. Then

$$X_{it} - X_{it-1} = \sigma \sqrt{\lambda_i \left(\frac{t}{T}\right) (\eta_{it} - \eta_{it-1}) + r_{it}},$$

where $|r_{it}| \leq C(1+|\eta_{it-1}|)/T$ with a sufficiently large C. Hence,

$$\frac{1}{T} \sum_{t=2}^{T} (X_{it} - X_{it-1})^2 = 2\sigma^2 \left\{ \frac{1}{T} \sum_{t=2}^{T} \lambda_i(t/T) \right\} + o_p(1)$$

Together with

$$\frac{1}{T}\sum_{t=1}^{T}X_{it} = \frac{1}{T}\sum_{t=1}^{T}\lambda_{i}(t/T) + o_{p}(1),$$

we get that $\hat{\sigma}_i^2 = \sigma^2 + o_p(1)$ for any i and thus $\hat{\sigma}^2 = \sigma^2 + o_p(1)$.

Notation

In order to proceed with the proof, we will need the following notation:

$$\hat{\psi}_{ijk,T} = \frac{\sum_{t=1}^{T} 1(\frac{t}{T} \in \mathcal{I}_{k})(X_{it} - X_{jt})}{\hat{\sigma}\left\{\sum_{t=1}^{T} 1(\frac{t}{T} \in \mathcal{I}_{k})(X_{it} + X_{jt})\right\}^{1/2}}$$

$$\hat{\psi}_{ijk,T}^{0} = \frac{\sum_{t=1}^{T} 1(\frac{t}{T} \in \mathcal{I}_{k}) \sigma \overline{\lambda}_{ij}^{1/2}(\frac{t}{T})(\eta_{it} - \eta_{jt})}{\hat{\sigma}\left\{\sum_{t=1}^{T} 1(\frac{t}{T} \in \mathcal{I}_{k})(X_{it} + X_{jt})\right\}^{1/2}} \quad \hat{\Psi}_{T}^{0} = \max_{(i,j,k)} a_{k}(|\hat{\psi}_{ijk,T}^{0}| - b_{k})$$

$$\psi_{ijk,T}^{0} = \frac{1}{\sqrt{2Th_{k}}} \sum_{t=1}^{T} 1(\frac{t}{T} \in \mathcal{I}_{k})(\eta_{it} - \eta_{jt}) \qquad \Psi_{T} = \max_{(i,j,k)} a_{k}(|\psi_{ijk,T}^{0}| - b_{k})$$

$$\phi_{ijk,T} = \frac{1}{\sqrt{2Th_{k}}} \sum_{t=1}^{T} 1(\frac{t}{T} \in \mathcal{I}_{k})(Z_{it} - Z_{jt}) \qquad \Phi_{T} = \max_{(i,j,k)} a_{k}(|\phi_{ijk,T}| - b_{k})$$

Nonparametric comparison of epidemic time trends: the case of COVID-19

1. We prove that $\left|\hat{\Psi}_{T}^{0} - \Psi_{T}\right| = o_{\rho}(r_{T})$, where $\{r_{T}\}$ is some null sequence.

- 1. We prove that $|\hat{\Psi}_T^0 \Psi_T| = o_p(r_T)$, where $\{r_T\}$ is some null sequence.
- 2. With the help of results from Chernozhukov et al. (2017), we prove

$$\sup_{q\in \mathsf{R}} \Big| \mathrm{P}\big(\Psi_{\mathcal{T}} \leq q\big) - \mathrm{P}\big(\Phi_{\mathcal{T}} \leq q\big) \Big| = o(1)$$

- 1. We prove that $|\hat{\Psi}_T^0 \Psi_T| = o_p(r_T)$, where $\{r_T\}$ is some null sequence.
- 2. With the help of results from Chernozhukov et al. (2017), we prove

$$\sup_{q\in \mathsf{R}} \left| \mathrm{P} \big(\Psi_{\mathcal{T}} \leq q \big) - \mathrm{P} \big(\Phi_{\mathcal{T}} \leq q \big) \right| = o(1)$$

3. By using these two results, we now show that

$$\sup_{q \in \mathbb{R}} \left| P(\hat{\Psi}_{T}^{0} \le q) - P(\Phi_{T} \le q) \right| = o(1)$$
 (2)

- 1. We prove that $|\hat{\Psi}_T^0 \Psi_T| = o_p(r_T)$, where $\{r_T\}$ is some null sequence.
- 2. With the help of results from Chernozhukov et al. (2017), we prove

$$\sup_{q\in R} \left| \mathrm{P}\big(\Psi_{\mathcal{T}} \leq q\big) - \mathrm{P}\big(\Phi_{\mathcal{T}} \leq q\big) \right| = o(1)$$

3. By using these two results, we now show that

$$\sup_{q \in \mathbb{R}} \left| P(\hat{\Psi}_{T}^{0} \le q) - P(\Phi_{T} \le q) \right| = o(1)$$
 (2)

4. It can be shown that $P(\Phi_T \leq q_{Gauss}(\alpha)) = 1 - \alpha$. From this and (2), it immediately follows that

$$P(\hat{\Psi}_{\mathcal{T}}^0 \leq q_{\mathsf{Gauss}}(\alpha)) = 1 - \alpha + o(1),$$

which in turn implies the desired statement.

Idea behind a_k and b_k

Dümbgen and Spokoiny (2001): the critical values $c_{ijk}(\alpha)$ depend on the scale of the testing problem, i.e. the length h_k of the time interval.

Dümbgen and Spokoiny (2001): the critical values $c_{ijk}(\alpha)$ depend on the scale of the testing problem, i.e. the length h_k of the time interval.

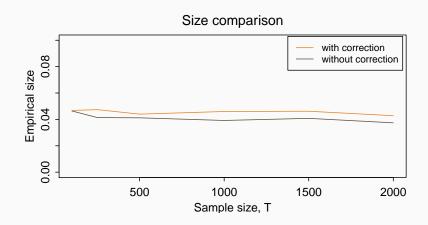

Specifically,

$$c_{ijk}(\alpha) = c(\alpha, h_k) := b_k + q(\alpha)/a_k,$$

where $a_k = \{\log(e/h_k)\}^{1/2}/\log\log(e^e/h_k)$ and $b_k = \sqrt{2\log(1/h_k)}$ are scale-dependent constants and $q(\alpha)$ is chosen such that we control FWER.

Idea behind a_k and b_k , part 2

This choice of scale-dependent constants helps us balance the significance of hypotheses between the time intervals of different lengths h_k :

Nonparametric comparison of epidemic time trends: the case of COVID-19

Consider the uncorrected Gaussian statistic

$$\Phi^{\mathrm{uncor}} = \max_{(i,j,k)} |\phi_{ijk}|$$

Consider the uncorrected Gaussian statistic

$$\Phi^{\mathsf{uncor}} = \max_{(i,j,k)} |\phi_{ijk}|$$

and let the family of intervals be

$$\mathcal{F} = \big\{ [(m-1)h_I, mh_I] \text{ for } 1 \leq m \leq 1/h_I, 1 \leq I \leq L \big\}$$

Consider the uncorrected Gaussian statistic

$$\Phi^{\mathsf{uncor}} = \max_{(i,j,k)} |\phi_{ijk}|$$

and let the family of intervals be

$$\mathcal{F} = \big\{[(m-1)h_I, mh_I] \text{ for } 1 \leq m \leq 1/h_I, 1 \leq I \leq L\big\}$$

Then we can rewrite the uncorrected test statistic as

$$\Phi^{\text{uncor}} = \max_{\substack{i,j \\ 1 \le m \le 1/h_l}} \max_{\substack{1 \le l \le L, \\ 1 \le m \le 1/h_l}} \left| \frac{1}{\sqrt{2Th_l}} \sum_{t=1}^{T} 1\left(\frac{t}{T} \in [(m-1)h_l, mh_l]\right) (Z_{it} - Z_{jt}) \right|$$

Consider the uncorrected Gaussian statistic

$$\Phi^{\mathsf{uncor}} = \max_{(i,j,k)} |\phi_{ijk}|$$

and let the family of intervals be

$$\mathcal{F} = \big\{[(m-1)h_I, mh_I] \text{ for } 1 \leq m \leq 1/h_I, 1 \leq I \leq L\big\}$$

Then we can rewrite the uncorrected test statistic as

$$\Phi^{\text{uncor}} = \max_{\substack{i,j \\ 1 \le m \le 1/h_l}} \max_{\substack{1 \le l \le L, \\ 1 \le m \le 1/h_l}} \left| \frac{1}{\sqrt{2Th_l}} \sum_{t=1}^{l} 1\left(\frac{t}{T} \in [(m-1)h_l, mh_l]\right) (Z_{it} - Z_{jt}) \right|$$

 \Rightarrow max_m... = $\sqrt{2\log(1/h_l)} + o_P(1) \to \infty$ as $h \to 0$ and the stochastic behavior of Φ^{uncor} is dominated by the elements with small bandwidths h_l . Go back
